

# Das2 PyServer 2.2 - User's Reference

Revision 2019-08-21

Purpose	Who	Date
Initial Draft	C. Piker	2015-03-18
Updates to allow for hourly and yearly cache blocks	C. Piker	2017-05-19
Updates to align with current versions for das2 library and tools	C. Piker	2017-07-28
Bumped version number, install instruction updates	C. Piker	2018-03-05
Included Server-Reader interface as this has been removed from ICD	C. Piker	2019-08-20

Acronym	Meaning
CGI	Common Gateway Interface, A definition of how programs invoked via a Web-Server should interact with that Web-server. See RFC-3875 at http://www.ietf.org/rfc/rfc3875.
DSDF	Data Set Descriptor File, A file defining a Das 2.2 data source for use via das2-pyserver.
HTTP	HyperText Transfer Protocol, The basic transport protocol for most of the world's data.
IDL	Interactive Data Language, a proprietary software language from Harris Geospatial Solutions, Inc.
NFS	Network File System - A longstanding Linux/Unix file sharing protocol
SDDAS	Southwest Data Display and Analysis System

#### A note on UTF-8

Das2 was developed by English speaking programmers, and thus has not been tested under non English locales. Despite this history, it is the desire of the das2 developers that the software should work with labels and descriptions in any language and thus UTF-8 is taken as the default encoding for all text handling. Please report any problems you encounter with text containing unicode characters at code points above 127. Bugs of this nature will be dealt with promptly.

#### 1: Overview

Das2 servers typically provide data relevant to space plasma and magnetospheric physics research. To retrieve data, an HTTP GET request is posted to a das2 server by a client program and a self-describing stream of data values covering the requested time range, at the requested time resolution, is provided in the response body.

This software, das2-pyserver, provides a caching middleware layer between server-side das2 readers, which stream data at full resolution to their standard output channel, and remote client programs such as Autoplot or SDDAS. The server handles common operations such as network transport, data reduction, authentication and caching, but it relies on specialized reader programs for full resolution data streams.

When using das2-pyserver, the two part das2 client-server system become a three part client-server-reader system. Each part is described below in order of increasing "distance" from the original data files:

- 1. One or more **readers**. These programs read data from some source and provide it in a standardize format. Readers are accompanied via Data Source Definition Files (DSDFs) which tells das2-pyserver how to run the reader.
- 2. **Das2-pyserver**. This software. It is run via Apache and provides responses for HTTP GET queries. Depending on the information requested and the server configuration, the response may be generated from internal information, or by running a reader.
- 3. One or more **clients**. These programs are the end destination for the data stream, and are typically plotting programs such as Autoplot or SDDAS, but maybe custom analysis scripts written in Python or IDL.

When handling das 2.2 *Discovery* and *Source* queries only the DSDF files are read. Readers are not run, this information flow is depicted in figure 1.1.

Figure 1.1: Server handling a das2 discovery query, information source in yellow

When handling a query for un-cached data values, the server runs an external reader program. Depending on the details of the request, a data reduction program may also be inserted into the output pipeline. This information flow is depicted in figure 1.2.

Figure 1.2: Server handling a das2 data query, information source in yellow

If data are requested for a time range that has been cached, the server may not run the reader at all. This is useful when long time ranges are requested or when a reader program is particularly inefficient. Whenever the server receives a request for data it checks the data source's DSDF file to see if caching is allowed. If so, das2-pyserver enters a cache request into a Redis job queue and then continues on to supply data is the standard fashion as described above. Subsequent requests for the same time range and similar resolution will read from the cache block files as depicted in figure 1.3. Depending on the details of the data request this can *significantly* reduce the time needed to satisfy the request.

Figure 1.3: Handling a das2 data query using the pre-reduced cache, information source in yellow

The first das 2 server program was a single-page CGI perl script written in 2002 in support of the University of Iowa's RPWS investigation on board the Cassini spacecraft as part of the das2 data display project. The python version was initially created in support of the EMFISIS instrument on board the twin Van Allen Probes and deployed at the University of New Hampshire. The caching subsystem was written to support the Waves instrument on the Juno mission to Jupiter. As of September 2019, primary data from at least 16 space based instruments and ground observatories as well as location and attitude information are available from various installations of the das2-pyserver software. Das2 client programs and libraries include, but are not limited to, Autoplot<sup>1</sup>, SDDAS<sup>2</sup>, das2py<sup>3</sup>, and das2pro<sup>4</sup>.

#### 2: Installation

Compilation and installation of das2-pyserver software currently requires a Linux environment. That can change if there is ever a demand for using the software on Windows or MacOS.

## 2.1: Prerequisites

Insure that the following programs are installed on your system before beginning the installation procedure.

- 1. Python  $\ge$  2.6, or Python  $\ge$  3.4
- 2. Apache2, any remotely recent version
- 3. Redis, known to work with version 3.2 or higher
- 4. redis-py, known to work with version 2.10 or higher
- 5. libdas2.3, latest version recommended

Since libdas2 provides small binaries needed by das2-pyserver, and since there are no pre-built libdas2.3 packages, installation instructions for both libdas2 and das2-pyserver are included below. In these instructions the '\$' character is used at the beginning of a line to indicate commands that you'll need to run in a Bourne compatible shell (bash, ksh, etc.).

Example prerequisite package installation commands are provided below for CentOS 7 ...

```
$ sudo yum install gcc subversion git
$ sudo yum install expat-devel fftw-devel openssl-devel
$ sudo yum install python3 python3-numpy python3-devel # or python2 equ.
$ sudo yum install redis
$ sudo pip3 install redis # if using python3
# --or--
$ sudo yum install python2-redis # if using python2
```

... and Debian 9

```
$ sudo apt-get install gcc subversion git
$ sudo apt-get install libexpat-dev libfftw3-dev libssl-dev
$ sudo apt-get install python3-dev python3-distutils python3-numpy # or py2 eq
$ sudo apt-get install redis-server
$ sudo apt-get install python3-redis # or python2 equivalent
```

#### 2.2: Get the Source Code

For now, some of the sources are in a University of Iowa SVN server and some are on github.com. All sources will be moved to github.com as time permits.

```
$ svn co https://saturn.physics.uiowa.edu/svn/das2/core/stable/libdas2_3
$ git clone https://github.com/das-developers/das2-pyserver.git
```

#### 2.3: Build and Install

Decide where your das2-pyserver code and configuration information will reside. In the example below the directory /usr/local/das2srv is selected, but you can choose any location you like. These

environment variables will be used through out the setup, so leaving your terminal window open though the testing stage will save time.

```
$ export PREFIX=/usr/local/das2srv
                                    # Adjust to taste
$ export PYVER=3.6
                                    # or 2.7, or 3.7 etc.
                                    # omit per-OS sub-directories
$ export N ARCH=/
$ export SERVER ID=solar orbiter 2 # for ex. ID should not contain white space
```

Test your PYVER setting by making sure the following command brings up a python interpreter:

```
$ python$PYVER
```

The following sequence will build, test, and install libdas2.3 and das2py if you have all prerequisite libraries installed:

```
$ cd libdas2 3
$ make
$ make test
$ make pylib
$ make pylib test
$ make install
$ make pylib install
```

Now build and install the python module and example configuration files. Set --install-lib and --prefix as indicated, unless you want to hand edit das2server.conf after installation. There is no need to run build before this step.

```
$ cd ../das2-pyserver
$ python${PYVER} setup.py install --prefix=${PREFIX} \
  --install-lib=${PREFIX}/lib/python${PYVER}
```

Copy over the example configuration file:

```
$ cd $PREFIX/etc
$ cp das2server.conf.example das2server.conf
```

## 2.4: Configure Apache

Apache configurations vary widely by Linux distribution and personal taste. The following procedure is provided as an example and has been tested on CentOS 7.

First determine which directory on your server maps to an Apache HTTPS CGI directory. To do this inspect /etc/httpd/conf/httpd.conf (or similar). The default is /var/www/cgi-bin. To provide better URLs for your site add the line:

```
ScriptAlias /das/ "/var/www/cgi-das/"
```

directly under the line:

```
ScriptAlias /cgi-bin/ "/var/www/cgi-bin/"
```

inside the <IfModule alias module> section of httpd.conf.

Then provide configuration information for your /var/www/cqi-das directory inside the /etc/httpd/conf.d/ssl.conf file. We're editing the ssl.conf instead of httpd.conf because das2 clients may transmit passwords.

8

```
<Directory "/var/www/cgi-das">
  Options ExecCGI FollowSymLinks
 # Make sure Authorization HTTP header is available to Das CGI scripts
 RewriteRule ^ - [E=HTTP_AUTHORIZATION:%{HTTP:Authorization}]
 RewriteEngine on
 AllowOverride None
 Allow from all
  Order allow, deny
</Directory>
```

By default, authorization headers are not made available to CGI scripts. The re-write rule above allows the Authorization header to be passed down to the das2 srvegi main script. This is needed to allow your server to support password protected data sources.

Now symlink the top level CGI scripts into your new CGI directory. Choose the name of the symlink carefully as it will be part of the public URL for your site:

```
$ cd /var/www/cgi-das
$ sudo ln -s $PREFIX/bin/das2_srvcgi_main server
$ sudo ln -s $PREFIX/bin/das2 srvcgi logrdr log
```

Set the permissions of the log directory so that Apache can write logging information:

```
$ chmod 0777 $PREFIX/log # Or change the directory ownership
```

Finally, trigger a re-read of the Apache's configuration data:

```
$ sudo systemctl restart httpd.service
$ sudo systemctl status httpd.service
```

#### 2.5: Test the Server

Test the server by pointing your web browser at the following two locations:

```
https://localhost/das/server
https://localhost/das/log
```

If this works, try browsing your new server with Autoplot (http://autoplot.org) or SDDAS (http://www.sddas.org).

If you are using Autoplot, copy the URI below into the Autoplot address bar

```
vap+das2server:https://localhost/das/server
```

and then click the green "Go" button. A dialog box similar to the one in figure 2.1 should appear.

If you are using SDDAS select start gPlot. In the main window click "Sources", then in the sources dialog select Add | Das2. Change the URL in the Das2 Source dialog to:

```
https://localhost/das/source
```

and click the "..." button. You should see a server browse dialog similar to figure 2.2.

Figure 2.1: Browsing a new das2-pyserver installation in Autoplot

Figure 2.2: Browsing a new das2-pyserver installation in SDDAS

The server comes preconfigured with a set of example data sources. Try to load and display a few of these. The Random example should always work no matter the given time range. For the others example times are provided and should be selected in the manner appropriate to your das2 client program.

#### 2.6: Basic Customization

When das2-pyserver is initially installed it has no site name, no logo, has no knowledge of any peer servers, no user names or groups and all cache files are written under the installation directory, thus some post-install customization is in order. All top-level programs supplied with the server have a compiled in default location for the configuration file:

#### \$PREFIX/etc/das2server.conf

Here \$PREFIX is whatever location you selected for the PREFIX variable in section 2.3 above. This file controls most of the operations of the server. The default configuration file is heavily commented so changing the value should be relatively easy.

#### 2.6.1 Server Identification

Set the following values in das2server.conf to identify your site, and server.

- Set the site identification by changing the value of **SITE\_NAME**
- Set the contact information by changing **CONTACT EMAIL** and **CONTACT URL**.

Then replace the file:

#### \$PREFIX/static/logo.png

with a small image that can be used identify your server in a list of das2 servers.

#### 2.6.2 Logging Setup

By default the das2 srvegi main program writes log information into the directory:

#### \$PREFIX/log

Since this program is run by Apache the log directory must be writable by whichever account is used to run Apache on your computer. To avoid having an Apache writable directory under \$PREFIX set the value LOG\_PATH in das2server.conf to another location.

By default only the local computer is allowed to view logging information at the address:

#### https://localhost/das/log

This is fine if your das2-pyserver instance is running on your workstation, but not useful if you've installed the software to a remote server. The list of addresses allowed to view log information is configured by the **VIEW\_LOG\_ALLOW** value. Change this if needed to allow connections from your local workstation.

#### 2.6.3 User Authentication

#### **TODO**

#### 2.6.4 Library and Run Paths

Before running any sub-programs, das2-pyserver top-level programs add any paths listed in **BIN\_PATH** to the *front* of the sub-program's PATH environment variable. If you have readers than are in a directory other than \$PREFIX/bin and don't want to specify complete path information in your DSDFs then add extra directories here.

Also before running an sub-programs, das2-pyserver top-level programs add any paths listed in **LIB\_PATH** to the front of the sub-program's LD\_LIBRARY\_PATH environment variable. If your readers depend on libraries that are not automatically locatable by your operating system's program loader you can add extra paths here.

Note that internally das2-pyserver top-level programs also use **BIN\_PATH** and **LIB\_PATH** so unless you know what you're doing it's best to append to these variables instead of over-writing them.

#### 2.6.5 Peer Servers

Das2-pyserver uses the file:

#### \$PREFIX/etc/das2peers.ini

to provide the information needed to satisfy the das2 Peers Query. An example file is include with the basic installation. Copy and customize this file to your liking.

- \$ cd \$PREFIX/etc
- \$ cp das2peers.ini.example das2peers.ini

Note this is read as a UTF-8 file so go ahead and add non 7-bit ASCII characters if you like.

## 3: Data Source Configuration

Das2-pyserver does not read data files directly. Instead it runs programs called readers, which are given query parameters on their command line, gather data from an input source, and emit data streams on their standard output channel. Readers are independent programs, thus they can be written in any language executable by the host operating system.

## 3.1: Reader Program Command Line Interface

Das2-pysever readers are always stand alone programs which must support one of the following command line patterns:

- 1. program MIN\_TIME MAX\_TIME [ EXTRA\_PARAMETERS... ]
- 2. program SAMPLING\_INTERVAL MIN\_TIME MAX\_TIME [ EXTRA\_PARAMETERS... ]

#### Where:

- program any string executable by /bin/sh, including pipe (i.e "|") characters.
- SAMPLING\_INTERVAL For readers marked as requiring time interval values (see requiresInterval below), this is the expected time interval between data points. The value is an ASCII floating point positive real number greater than 0.0 in units of seconds.
- MIN\_TIME The inclusive lower bound UTC time of the query interval. The value should be an ISO-8601 time point string.
- MAX\_TIME The exclusive upper bound UTC time of the query interval. The value should be an ISO-8601 time point string.
- EXTRA\_PARAMETERS Optional extra parameters sent by the das2 client program. There are no restrictions on these parameters, however pyserver will check them for shell and SQL escapes. The extra parameters passed to a program may be specified as multiple arguments or they may arrive as a single quoted argument with space separated sub-components.

Version 2.2 of das2-pyserver only supports data queries over time, and the command line interface between the server and the reader reflects this limitation. For now, queries over other physical parameters such as latitude and longitude are not supported. A more general command line interface is planned for version 2.3 of the software.

## 3.2: Data Source Definition Files (DSDF)

In order to identify the programs that will supply data streams, das2-pyserver depends on small text files called *Data Source Definition Files* (DSDF). DSDFs serve two purposes on a das2-pyserver:

- 1. They supply the information used to satisfy *Discovery* and *Source* queries from the das2.2 ICD without running any additional sub programs.
- 2. Internal keywords such as reader and reducer are used to tell das2-pyserver how to produce, reduce, and cache data, and thus satisfy *Data* queries.

The root directory containing the data source definition tree is determined by the **DSDF\_ROOT** keyword in the das2server.conf file.

Data source definition files must end in the suffix:

.dsdf

or das2-pyserver will ignore them.

#### 3.2.1 DSDF format

Though the server is written in python, DSDFs use IDL syntax, thus strings are marked by single quotes ('), a semicolon ';' represents the start of a comment, and comments run to the end of the line. Each non-comment line in the must follow the

```
keyword = value
```

pattern. Das2-pyserver ignores any keywords not required for it internal operations. Thus any keyword may be used, so long as it contains only the characters a-z, A-Z, 0-9 and the underscore, \_. A reference of keywords understood by the server and a description of their values is provided in section 6.2.

## 3.3: Example DSDFs

Since most people learn by example, this section provides a variety of DSDFs each focused on a particular aspect of defining a data source.

#### 3.3.1 Minimal Example

The following is a minimal DSDF, only the bare minimum keywords are present. The reader is assumed to follow command line pattern 1 from section 3.1 above and that it uses the default reducer as specified in das2server.conf.

```
description = 'A data source description'
reader = '/path/to/some/program'
das2Stream = 1
techContact = 'Able Tech <able-tech@somewhere.edu>'
exampleRange_00 = '2017-09-15 to 2017-09-16'
```

Listing 3.1: Minimal DSDF

#### 3.3.2 Non-default data reducer

The following file Voyager PWS file tells das2-pyserver how to run the data reader, which reducer should be used to handle long time ranges, and provides a few example times to get to interesting data quicker. The required keywords are in **bold** font.

```
description = 'Electric Field averages and peaks from the Voyager 1 PWS SA'
techContact = 'Jane Doe <jane-doe@uiowa.edu>'
sciContact = 'Dr. Scientist <doc-sci@uiowa.edu>'

reader = '/usr/local/das2srv/bin/vgpw_sa_rdr 1'
das2Stream = 1
reducer = 'das2_bin_peakavgsec'

validRange = '1977-09-05 to now'
exampleRange_00 = '2014-08-31 to 2014-09-01|Latest Data'
exampleRange_01 = '1979-03-01 to 1979-04-14|Jupiter Encounter'
exampleRange_02 = '1980-11-10 to 1980-11-14|Saturn Encounter'
```

Listing 3.2: DSDF using a non-standard reducer

Unlike the das2\_bin\_avgsec reducer which only outputs average values, the das2\_bin\_peakavgsec reducer outputs two data variables for each data variable in the input. One is a variable of averages, the other contains bin peaks. The result of using this reducer can be seen in figure 3.1 which was generated by displaying long duration Voyager 1 PWS spectrum analyzer data in Autoplot. The gray peaks are the maximum values generated for each bin, and the black fill represents the average value.

Figure 3.1: Using the das2 bin peakaygsec reducer for data, and an interval reader for X annotations

#### 3.3.3 Interval Data Source

The following Juno Ephemeris DSDF is for an interval based data source. Interval sources are typically the output of mathematical models. In this case, the data are produced by SPICE calculations. Since this is an interval source, the reader must follow command line pattern 2 from Section 3.1. Interval sources directly provide data at the required resolution, the special flag not\_reducible is set in Listing 3.3 to insure that the server does not pass the output of the reader through a reducer.

Listing 3.3: DSDF specifying an interval based reader

Also, notice the characters "HGI" in for the reader value. Das2-pyserver adds command line

arguments after whatever string is provide for the reader value. Thus, fixed command line arguments may be provided to the reader so long as these occur **before** the arguments supplied by das2-pyserver when invoking the reader. An interval based source, much like this one, was used to provide X-axis annotations for the Figure 3.1 above.

#### 3.3.4 Protected Data Sources

TODO: Authentication example

#### 3.3.5 Cache Directives

The following data source provides ground based radio astronomy measurements from the first Long Wave Array station (LWA-1) of Jupiter. Since ground stations typically emit far more data than spacecraft over a similar measurement scales these data are cached at varying resolutions so that graphical data set navigation is practical. To add to the complications, this reader is able to produce data for the low tuning of the LWA (10 to 30 MHz) and the high tuning (20 to 40 MHz). By default the reader outputs the low tuning, but if supplied with an optional EXTRA PARAMETER on the command line (see Section 3.1) that reads "high" it will output the high tuning.

```
= 'LWA-1 Jupiter, Stokes I Parameter at High and Low Tunings'
description
techContact
                 = 'Jane Doe <iane-doe@gsfc.nasa.gov>'
sciContact
                 = 'Masafumi Imai <not-his@real.address.edu>'
                 = '/usr/local/bin/lwa1 l2drx rdr'
reader
das2Stream
                 = 1
                 = 'high | Output the 20-40 MHz range instead of 10-30 MHz'
param 00
exampleRange 00 = '2015-02-21 to 2015-02-22 \mid Low Tuning (1.1 TB)'
exampleRange 01 = 2015-02-21 to 2015-02-22 | High Tuning (1.1 TB)
exampleParams 01 = 'high'
cacheLevel 00 = '10 ms | persecond'
                                           ; caching low-tuning (default) values
cacheLevel 01 = '50 ms | perminute'
cacheLevel_02 = '250 ms | perminute'
cacheLevel 03 = '1 s | hourly'
cacheLevel_0^-4 = '5 s | daily'
cacheLevel 10 = '10 ms | persecond | high'
                                              : caching high-tuning values
cacheLevel 11 = '50 ms | perminute | high'
cacheLevel_12 = '250 ms | perminute | high'
cacheLevel_13 = '1 s | hourly | high'
cacheLevel 14 = '5 s | daily | high'
```

Listing 3.4: An example of deep multi-resolution cache configuration with EXTRA PARAMETERS

## 3.4: Reader output

Readers are expected to output a compliant das2 or Q stream as defined in the Das2.2 Interface Control Document. Binary das2 output is recommended since das2-pyserver can convert this to text format on request (see section 5.3) or convert the output to HAPI format (section 5.2) if desired by the client program.

Unfortunately, there are many data sets that the das 2.2 stream format cannot represent, for example any

Das2: PyServer User's Guide

data sets that contain text data and any arrays higher than rank 2. Until an upgraded das2 stream format is supported by libdas2, das2-pyserver, das2pro and Autoplot, readers should output Q streams in these cases. Q streams are understood by Autoplot which is the most commonly used das2-pyserver client.

## 4: Data Cache Configuration

Typically Das2 Servers exist to feed data to graphical clients. In many situations the data stored on disk are more detailed that an application can display. Take for example a magnetometer than produces one measurement every quarter of a second. Typically a scientist will want to view all data for a particular day, or maybe all data for a multi-day orbit. For our hypothetical instrument, a day's measurements are 345,600 data points. Since an average computer screen is only around 2000 pixels wide sending a whole day's worth of measurements at intrinsic resolution is a waste of network bandwidth and client memory.

As part of the Das2 Client-Server protocol (see the Das 2.2 ICD), client programs may inform the server of the minimum resolution that is expected with each data request. To make better use of resources the Das2 servers use the resolution information to reduce data streams on the server before transmission to the remote client. This makes life easier on the client program, however it does nothing to conserve compute resources on the server. All relevant high resolution files must be read by reader programs for each request, and reduction calculations must be re-run for each client request. To solve this problem, the Das2 PyServer can be directed to cache reduced data streams, but to do so in a multi-process environment, a task queue system is needed.

## 4.1: Redis task queue

## 4.2: Enabling a data cache

Caching is controlled via keywords in the DSDF file that defines each data source on the Das2 server. The keywords that affect the data cache are given in table 4.1 below.

DSDF Keyword	Purpose
reader	Defines the program to run to produce intrinsic resolution data.
reducer	This is the program which generates the reduced resolution datasets. If not specified a default will be used, based off the stream type. If set to not_reducible, then only intrinsic resolution caches may be created.
das2Stream	Let's the server know that the data set reader produces Das2 Streams. Different default reducers, cache writers an cache readers are invoked for different stream types.
qstream	Let's the server know that the data set reader outputs information in QStreams format. Again this affects the default reducer and cacheReader.
cacheLevel_XX	Defines the number of resolution levels in the cache and the file storage method used for each one. Each level may specify a resolution in seconds, or intrinsic to indicate that reader output should be cached, but not reduced.
cacheReader	This option is rarely used. It allows an alternate cache reader program to be specified.

Table 4.1: DSDF keywords involved in server side caching

## 4.3: Cache Layout

The following rules are used by Das2 PyServer to store and retrieve files from the disk cache. These are provided in case that you need to manually manipulate the cache, or for writing replacement cache readers.

Reduced resolution files are found using the following directory path:

CACHE ROOT / dataset name / norm params / res dir / block dirs / block file

Table 4.2 below breaks out each component of a cache file path.

Path Component	Description	Input Source	
CACHE_ROOT	The root of the pre-reduced data file tree	das2server.conf	
dataset_name	The dataset name on the server. Note that dataset names are hierarchical. Each section of the name becomes a path component.	client query	
param_string	This is a <b>normalized</b> parameter string, thus all spaces and other dangerous components have been transformed into alternate characters. This string does <b>not</b> include the data range query paramentes (typically a begin and end time). See part 4.3.1 of this section for normalization rules.	client query	
res_dir	This directory corresponds to the resolution of the reduced data.  • For binned data, the name is the prefix <b>bin-</b> concatenated with the resolution value (no units).  • The server can also cache intrinsic resolution data. In this cane the resolution directory is just named ' <b>intrinsic</b> '. This is a useful optimization when dealing with slow reader programs.	dataset DSDF file	
block_dirs	These path components are based on the resolution's coverage blocks. For example if the 'daily' coverage blocks are selected for a resolution in the DSDF file then this would be just be a single directory containing the 4-digit year. See part 4.3.2 of this section for the available schemes.	dataset DSDF file	
block_file	The filename is produced as follows: coverage_resolution.suffix where coverage is scheme dependent, resolution is the same string found in the resolution_dir component above, and suffix depends on the file format, either d2s or qds for Das2 streams and QStreams respectively. See part 4.3.2 of this section for the available coverage blocks.	dataset DSDF file	

Table 4.2: Cache File Path Components

#### 4.3.1 Normalized Parameter Strings

todo: document the normalization algorithm

Das2: PyServer User's Guide

#### 4.3.2 Available Coverage Blocks

Currently only time series data may be arranged into coverage periods. This meets must current needs but should be expanded to handle measurements such as radar returns that correlate with locations on a planetary surfaces.

Coverage Blocks	Directory Pattern	File Name Prefix	Partial Path Example
persecond	YYYY/MM/DD/HH/MM	YYYY-MM-DDTHH-MM-SS_	<b>2013/10/31/01/05/</b> 2013-10-31T01-05-57_bin-10ms.d2s
perminute	YYYY/MM/DD/HH	YYYY-MM-DDTHH-MM_	<b>2013/10/31/01/</b> 2013-10-31T01-05_bin-1s.d2s
hourly	YYYY/MM/DD	YYYY-MM-DDTHH_	<b>2013/10/31/</b> 2013-10-31T01_bin-1s.d2s
daily	YYYY/MM	YYYY-MM-DD_	<b>2013</b> / <b>10</b> /2013-10-31_bin-60s.d2s
monthly	YYYY	YYYY-MM_	<b>2013</b> /2013-10_bin-3600s.d2s
yearly	(none)	YYYY_	2013_bin-86400s.d2s

Table 4.3: Times Series Cache Blocks

Das 2.2 servers are heavily targeted towards handling time series data. It is anticipated that new coverage block storage schemes will be needed to handle future Das 2.3 client queries.

### 5: Extra Services

santeou

#### 5.1: Server-side Plot creation

#### TODO: Edit

If you want to enable server-side plot generation un-comment:

```
PNG_MAKER = autoplot_url2png.py
```

in the das2server.conf configuration file and:

```
$ edit $PREFIX/bin/$N_ARCH/autoplot_url2png.py
```

to update any paths that might not make sense on your system. Any program can be used as a server side PNG creator as long as it follows the interface defined in Appendix C.

Currently the configuration file options:

```
DSID ROOT, LIB PATH and VIEWLOG2 RELPATH
```

don't do anything, you can comment them out or just ignore them.

Any program that can take as it's inputs the following command line parameters:

```
server=SERVER_NAME
dataset=DSDF_RELATIVE_PATH
start_time=BEGIN
stop_time=END
image=OUTPUT_FILE_NAME
param=EXTRA_PARAMS
```

and writes a PNG file to the given location can be used by the das2\_srvcgi\_main script to generate server-side plots which are then transmitted to the client instead of a numeric dataset. As an example, the command line parameters to request an EMFISIS High Frequency Receiver Dynamic Spectrum with noise spikes removed might look like:

```
your_program dataset=rbsp/RBSP-B/HFR_spectra.dsdf \
    start_time=2013-03-01 \
    end_time=2013-03-02 \
    image=/usr/local/das2srv/tmp/HFR_spectra_34578.png \
    params='KEEP-SPIKES Bu' \
    server=http://emfisis.physics.uiowa.edu/das/das2Server
```

An example wrapper script using the Autoplot program to create plot PNGs is provided in the source code for the server and is build when issuing the commands: "make aping" and "make install\_apimg".

## 5.2: HAPI Subsystem

sanethu

## **5.3: ASCII Output Conversion**

### 6: Server File Reference

### 6.1: Main Configuration: das2server.conf

All Das2 PyServer side programs whose name begins with 'das2\_srv' use the das2server.conf file to direct some or all of their actions. The location of this file for a particular Das2 PyServer is compiled into these programs during installation. The location of the file is:

#### \$PREFIX/servers/\$SERVER NAME/etc/das2server.conf

Here \$PREFIX and \$SERVER\_NAME are environment variables that were specified during installation and have no default values.

The server also depends various utility programs as well to handle tasks such as converting data streams to ASCII text, up-converting old Das 1 reader output to Das 2.2 format, and reducing data streams on the server before transmission to the client. Utility programs do not consult das2server.conf, but instead must receive all necessary configuration information on the command line.

The only hard-coded path on the server is the configuration file itself. All other locations, including the dataset root directory, the logging directory, the cache location and even the program and library paths are specified in the configuration file. The server is so flexible that the configuration file can even be used to swap in custom code for parts of the main CGI routine! Flexibility like this can break things. If you are having problem's on your server first run consult the logs. If that isn't helpful, try using a webbrowser to issue a debug query to the server which will look similar to:

http://your.host.top/cgi/path/das2Server?server=debug

This will cause das2-pyserver to dump it's configuration information to your browser.

**SITE\_IDENTITY** The name of this das2 server. Will be provided to clients that preform a Server ID

query on your site.

Default: None

**DSDF\_R00T** The path on your local file system to the top of the Data Set Definition file tree.

Default: \$PREFIX/servers/\$SERVER NAME/datasets

**CACHE\_ROOT** The path on your local file system to the top of the pre-reduced data set cache.

Default: \$PREFIX/servers/\$SERVER NAME/datasets

**RESOURCE\_ROOT** The path on your local file system to the top of the static file resource tree.

Default: \$PREFIX/servers/\$SERVER\_NAME/resources

**USER\_PASSWD** The path on your local file system to the user account password file

Default: \$PREFIX/servers/\$SERVER NAME/etc/passwd

**USER\_GROUP** The path on your local file system to the user account group file

Default: \$PREFIX/servers/\$SERVER NAME/etc/group

**TEST FROM** 

Default: None

#### 6.1.1 Default Reducer

The default data reduction programs are specified by the:

#### D2S\_REDUCER and QDS\_REDUCER

keywords inside das2server.conf. If unchanged from the example file, the program das2\_bin\_avgsec is set to be the reducer program for das2 streams, and no reducer is specified for Q streams.

Inside each DSDF, the keyword:

reducer

can be use to over-ride the server-wide default value.

## 6.2: Data Set Definition Files: \*.dsdf

Keyword	Required	Notes
description	yes	A human readable description of the data source.
summary	no	A longer form string describing data processing and other details of the source. The value for this keyword typically extends over many lines and thus makes use of the IDL string concatenation and line continuation syntax, i.e.:  'First line of value, ' + \$ 'second line of value.'
techContact	yes	An email address indicating who to contact if there is a problem with a reader. An example value: 'Some Person <some-person@uiowa.edu>'</some-person@uiowa.edu>
sciContact	no	An email address providing contact information for questions about scientific usefulness or interpretation of the data source.
reader	yes	An arbitrary string that provides the beginning portion of the command line needed to invoke the reader. Additional arguments are supplied by the server as defined in Section 3.1.
requiresInterval	maybe	Set to '1' to indicate that the server should supply the interval between measurements on the reader command line. This triggers use of command line pattern 2 as defined in Section 3.1. The first output time should be MIN_TIME and each successive time should be larger by the value of SAMPLING_INTERVAL.
das2Stream		If set to '1' then the reader produces a das2.2 stream as defined in the Das2.2 Interface Control Document. If the output is a QStream, this keyword should not be present.
qstream	conditional (yes, if reader outputs a Q stream)	If set to '1' the reader produces Q Streams (see section Error: Reference source not found for Q Stream formatting information). There is no need to include this keyword if the reader produces a Das2 Stream.
exampleRange_XX	<b>yes</b> (at least one)	An example time that is known to provide visible data. This is use by client programs to 'just get something on the screen'. There can be up to 100 example ranges. The format of this string field is as follows:  'START_TIME to END_TIME   NAME' using Voyager as an example:  exampleRange_01 = '1979-03-01 to 1979-04-14 Jupiter Encounter' exampleRange_02 = '1980-11-10 to 1980-11-14 Saturn Encounter' The ' Name' portion of the string is optional, but encouraged.

Keyword	Required	Notes
cacheLevel_XX	no	Some Das2 servers can store pre-reduced datasets. To direct the server to generate a set of pre-reduced datasets use this keyword. The value format is:  RESOLUTION   STORAGE_PERIOD [   PARAMS ]  Each resolution level of the cache is separated by ' ' (pipe) characters. A semicolon is placed between the resolution value and
		file duration value.
		• RESOLUTION is a Das2 datum string, typically given in seconds, or the keyword 'intrinsic' to indicate caching the highest resolution available from the data source.
		• FILE_PERIOD determines the coverage period of each cache file. For RESOLUTION Datums that have units of time, the following keywords may be used: <b>hourly</b> , <b>daily</b> , <b>monthly</b> . The format for caching based on data indexes other than time have not been established.
		<ul> <li>PARAMS A string of optional extra parameters to send to the reader when producing the cache.</li> <li>Example cacheLevel_XX values:</li> </ul>
		<pre>cacheLevel_00 = 'intrinsic   hourly'</pre>
		<pre>cacheLevel_01 = '1 s   daily'</pre>
		<pre>cacheLevel_02 = '60 s   daily   -r no-spikes'</pre>
		Cached datasets are generated via the reduction program specified in the <b>reducer</b> keyword thus if reducer = 'not_reducable' only 'intrinsic' resolution may be used when specifying cache levels. If any PARAMeters are specified, these are provided to the reader with underscores converted to spaces.
cacheReader	no	If this item is blank the default cacheReader for the output type (das2Stream or qstream) will be invoked to read the data cache
exampleInterval_XX	maybe	This keyword is required for each exampleRange when the reader requires an interval parameter.
exampleInterval	no	A synonym for exampleInterval_00.
exampleParams_XX	no	To specify a parameter set to provide to a reader when called for a given exampleRange use this keyword. This keyword is adds a reader parameter string to an associated exampleRange_XX keyword. Where the characters XX are replaced by the example number.
exampleParams	no	A synonym for exampleParams_00.
exampleRange	no	A synonym for exampleRange_00.

Keyword	Required	Notes
item_XX	no (recommended)	Used to name independent datasets in a stream. This allows a Das2 client to only load the individual planes of a Das2 stream, or individual datasets in a qdataset bundle. The format is:
		<pre>item_XX = 'ID [  DESCRIPTION]'</pre>
		In the following example the Das2 reader that produces magnetic X, Y, Z and Magnitude values each as a separate <y> vector.</y>
		<pre>item_00 = 'mag   Magnetic Field Magnitude' item_01 = 'x_gsm   X component in the GSM frame' item_02 = 'y_gsm   Y component in the GSM frame' item_03 = 'z_gsm   Z component in the GSM frame'</pre>
		For Das2 Streams, ID values above must match the <b>name</b> attribute value given in the <y>, <yscan> and <z> elements in the packet headers. See section Error: Reference source not found for more information an Das2 stream packet headers.</z></yscan></y>
		For QStreams, ID values above match the <b>id</b> attribute in <qdataset> elements in the packet headers. See section Error: Reference source not found for more information on QStream packet headers.</qdataset>
		Though this keyword is not required, it is strongly recommended for streams that produce more than one top-level dataset by default.
readAccess	no	This value controls when authorization is needed and who is authorized. The format of this field is:  'AUTH_METHOD:TEST [  AUTH_METHOD:TEST ]' here AUTH_METHOD is a token stating the authorization method and TEST is the value to test against. AUTH_METHOD may be one of AGE, GROUP or USER. If any one authorization method succeeds then access is granted. Thus authorization methods are combined using a logical OR test.
		An example for voyager follows:  readAccess = 'AGE:1y6m GROUP:voyager USER:don'  In this example data older that 18 months is automatically authorized, so is anyone in the group voyager, as well as the user don.
securityRealm	no	This string should be provided by a Das2 client to end-user that is providing the authentication token and provides a context-clue as to what password is expected. For example:
		securityRealm = 'Juno Magnetospheric Working Group'
		indicates that users in the MWG should have access to these associated data stream.

Keyword	Required	Notes
reducer	no	One of the key benefits of serving data via a program instead of directly transmitting files is that data reduction can take place on the server which can drastically reduce the network bandwidth required to produce a plot. There are three categories to the values for this keyword.  • If this keyword is not specified a default data-reduction program will process the reader's output stream. By default data are averaged in the streaming dimension (see sections Error: Reference source not found and Error: Reference source not found for a definition of the streaming dimension).  • If set to the value "not_reducible" no server-side data reduction will be preformed.  • If set to the name of a program on the server then that program will be used to reduce data in the streaming dimension before delivery.
rename	no	If a datasource is renamed this keyword may be used in the old copy of the datasource to point clients to the new location. DSDF files containing the keyword rename are included in the output of list and discovery queries. See section Error: Reference source not found for more information on list queries.
server	no	A das2 server can advertise the existence of data sets hosted via another das2 server. If this keyword is present and it's value doesn't match the URL of the server which was contacted, then the contacted server issues an HTTP redirect will to the client.
testInterval	maybe	This keyword is required if testRange is given and the reader requires an interval parameter.
testRange	no	A test time that is expected to provide unchanging visible data. It is use by automated end-to-end testing software to make sure that the output of a reader doesn't change over time.
validRange	no (recommended)	A time range over which the data source may produce output. The syntax is:  validRange = BEGIN to END  Instead of a timestamp, the END may be denoted by the case- insensitive word 'now' for on-going missions. The following example is for Voyager 1 PWS Waveform data:  validRange = '1977-09-05T00:00 to NOW'  Though not required, usage of this keyword is highly recommended.
AnyKeyword	no	Any other key = value pair may be included in the file but only the ones above have specific uses.

Table 6.1: DSDF Keywords

6.3: Server Peers: das2peers.ini

6.4: Authentication: passwd, group

Das2: PyServer User's Guide

## 7: Server Program Reference

## 7.1: Web Service Programs

#### 7.1.1 das2\_svrcgi\_main

**Purpose:** Main Das2 PyServer CGI program

Usage: das2 srvcgi main (All options are set via CGI/1.1 Environment Variables)

Scope: Server Specific Program

Config: das2server.conf, data set DSDF files

das2 svrcgi main is meant to be invoked by a web-server that supports the CGI/1.1 interface standard. Most of the program's activity is directed by two inputs:

- 1. The CGI environment variables associated with a client request
- 2. The contents of the das2server.conf file

At present the POST method is not handled by the program, so standard input is not read. Furthermore das2 svrcgi main does not write to standard error. All error messages out output as HTTP responses on standard output, as is expected of a CGI program. Configuration file details are provided in Section 5, environment variables used by this program are listed below.

<b>Environment Variable</b>	Summary				
HTTP_AUTHORIZATION	Used to authenticate client programs if a data source has the keyword				
(optional)	eadAccess in it's DSDF file. (See Das2.2 ICD, Table 5)				
HTTP_USER_AGENT	Used to determine if error messages should be output as Das2 Stream comments or as plain text.				
PATH_INFO	Used to determine which resource file a client program is trying to access.				
	(Das 2.3 protocol will use this for data source location as well)				
QUERY_STRING	Used to determine which action the client is requesting				
REMOTE_ADDR	Used to save log messages by remote IP address and for allowing some IP addresses to skip authentication all together				
REQUEST_METHOD	Current version merely checks to make sure POST is not in use.				
SCRIPT_NAME	Used to determine the URL to the Das2 PyServer itself				
SERVER_NAME	Used to determine the URL to the Das2 PyServer itself				
SERVER_PORT	Used to determine the URL to the Das2 PyServer itself				
SERVER_SIGNATURE	Used to advertise the underlying web-server software on auto-generated web pages.				

#### 7.1.2 das2 srvcqi loqrdr

**Purpose:** Log Reader CGI program

Usage: das2 srvcgi logrdr (All options are set via CGI/1.1 Environment Variables)

Scope: Server specific program

**Config:** das2server.conf

### 7.2: das2 ascii

**Purpose:** Server background processing manager

das2 srv arbiter [-h] [--no-daemon] **Usage:** 

Scope: Server specific program

Config: das2server.conf

## 7.3: das2 srv arbiter

**Purpose:** Server background processing manager

**Usage:** das2 srv arbiter [-h] [--no-daemon]

Scope: Server specific program

Config: das2server.conf

Handles Jobs received from the task queue broker. The format

## 7.4: das2\_srv\_passwd

**Purpose:** Manage user accounts for Das2 Servers

Usage: das2 srv passwd[-h][-c] [-b] username [password]

Server Specific Program Scope:

das2server.conf Config:

das2 srv passwd updates the file indicated by the USER PASSWD entry in a server's das2server.conf file. At present all password strings are stored using the CRYPT method. Das2 systems are assumed to operate in a somewhat friendly environment. Scientific data are usually not interesting to hackers, and user accounts on Das2 systems mostly exist to prevent premature publishing of data. For these reasons the crypt algorithm is considered sufficient to provide what little security is needed.

## 7.5: das2\_srv\_todo

**Purpose:** Adds tasks to a Das2 server's task lisk

#### Das2: PyServer User's Guide

Usage: das2 srv todo [-h] [--no-daemon]

**Scope:** Server specific program

**Config:** das2server.conf

Handles Jobs received from the task queue broker. The format

## 7.6: das2\_bin\_avg

**Purpose:** Reduces the size of Das2 streams by averaging over values in the first  $\langle x \rangle$  plane in a

stream.

Usage: das2\_bin\_avg [-b BEGIN] BIN\_SIZE

**Scope:** General Program

**Config:** (none)

## 7.7: das2\_bin\_avgsec

**Purpose:** Reduces the size of Das2 streams by averaging over time

Usage: das2\_bin\_avgsec [-b BEGIN] BIN\_SECONDS

**Scope:** General Program

**Config:** (none)

das2\_bin\_avgsec is a classic Unix filter, reading Das 2 Streams on standard input and producing a time-reduced Das 2 stream on standard output. The program averages <y> and <yscan> data values over time, but does not preform rebinning across packet types. Only values with the same packet ID and the same plane name are averaged. Within <yscan> planes, only Z-values with the same Y coordinate are combined.

It is assumed that <x> plane values are time points. For this reducer, only the following <x> unit values are allowed:

us2000 - Microseconds since midnight, January 1st 2000

t2000 - Seconds since midnight, January 1st 2000

mj1958 - Days since midnight January 1st 1958

t1970 - Seconds since midnight, January 1st 1970

All time values, regardless of scale, epoch, or representation in the input stream are handled as 8-byte IEEE floating point numbers internally. ASCII times are converted internally to us2000 values.

The BIN\_SECONDS parameter provides the number of seconds over which to average <y> and <yscan> plane values. Up to total of 99 <y> and <yscan> planes may exist in each packet type, and up to 99 packet types may exist in the input stream. This is a plane limit, not a limit on the total number of data vectors. <yscan> planes may contain an arbitrary number of vectors. The output stream has the same number of packet types and planes as the input stream, but presumably with many fewer time points.

#### **Option Summary** -b BEGIN Instead of starting the 0th bin at the first time value received, specify a starting bin. This

useful when creating pre-generated caches of binned data as it keeps the bin boundaries predictable.

## 7.8: das2 bin peakavgsec

## 7.9: das2\_cache\_rdr

**Purpose:** Pre-reduced dataset reader Usage: das2 srv cacherdr [-h] DATASET NAME NORM PARAMS RESOLUTION BEGIN END Scope: Server specific program das2server.conf, data set DSDF files Config:

das2\_cache\_rdr selects pre-generated das2 stream files from a hierarchical data cache of pre-binned data. Full path to cache files is:

CACHE ROOT/dataset name/norm params/resolution dir/block dirs

Parameter	Summary
DATASET_NAM E	The name of the dataset, i.e. the relative path to the DSDF file from the root of the DSDF tree.
NORM_PARAMS	A normalized string representing the parameters set to the reader. The assumption is that when readers are called with different parameter sets the output data set changes. Each different parameter set is a different set of cache files. The string '_noparam' can be used to indicate that no parameters were given to the reader when the cache files were generated.
	See section, part for a description of reader parameter string normalization.
RESOLUTION	An integer providing the resolution requested. The largest bin size that does not exceed this value will be selected as the dataset. The string 'intrinsic' can be used to select the best resolution available. Also a BINSZ of 0 may be given to select native resolution as well.
BEGIN	The starting value of the lookup parameter.
END	The ending value of the lookup parameter.

## 7.10: Readers

#### 8: Work Queue Reference

Section 7.3 introduced the program, das2 svr arbiter, which handles background processing requested by other components of a Das2 server. It produces cache files, generates coverage plots, collects usage statistics, etc. By default the program is run as a daemon listening for job requests from a work queue broker. Currently the only work queue broker supported is the Redis server.<sup>5</sup> Thus all remaining information in this section will assume that Redis is in use.

## 8.1: Input Work List: das2 todo

After starting, das2 svr arbiter opens a connection to the Redis server listed in the server configuration file, das2sever.conf, and issues a blocking right pop operation on the list variable, das2 todo. List values strings defining tasks to be handled and have the following format:

```
req time|reqester|requester ex|rmtreq|rmtreq ex|user|job cat|job fields...
```

Task strings always start with the following sub-fields which are delimited by pipe "characters."

- 0: req time An ISO-8601 time and date string to at least seconds resolution, example: 2015-03-25T10:37:43.334
- 1: requester An identifier of the program making the request. For example the URL to the das2server associated with the task may be used: http://planet.physics.uiowa.edu/das/das2Server
- 2: requester ex Extra information about the server, may be empty.
- 3: rmtreq Some programs, such as web servers handle request on behalf of remote clients. The IP of the client requesting the operation. Note this may the IP of the server itself if a work item was entered via the das2 srv todo program.
- **4:** rmtreq ex Extra information about a client, such as it's GeoIP location, may be empty.
- 5: user The user name, if any associated with the work request, may be empty
- 6: job cat The job category, may not be empty. Sections 8.1.1 through 8.1.3 below list the current job categories and the job-specific fields
- 7-N: job fields Each category of job has it's own list of fields following the job cat field. See Tables 8.1 through 8.3 for a description of each job category and the required fields.

Empty fields are represented by two adjacent pipes with no intervening characters. To make the protocol expandable, each job category has it's own field set. These are added at index 7 and continue as far as is dictated by the category.

#### 8.1.1 Build Cache Task

This task requests a cache build for a specified range of a dataset at one, or all of the resolutions listed in the dataset's DSDF file. This task type is specific to the Das 2.2 system interface. Upcoming Das 2.3 cache tasks will presumably require a different set of fields, or different field values.

Job Category Value: TASK CACHE

See http://redis.io for more information on Redis, and advanced key-value cache and store server.

Overall Field Index	Job Field Name	Job Field Description
7	dataset	The name of the dataset that needs to be cached. This is always the relative DSDF filename without the extension. Examples: juno/wav/survey, voyager/1/pws/SpecAnalyzer-4s-Efield
8	begin_index	The beginning index to cache, for Das 2.2 this is an ISO-8601 start time.
9	end_index	The ending index to cache, for Das 2.2 servers this is an ISO-8601 end time.
10	cache_level A requested cache level index. This maybe the keyword <b>ALL</b> , to indicate the all cache levels specified in the dataset's DSDF file are to be produced, or may be one of the given cache index values. See the <b>cacheLevels_XX</b> Divalue in Section 3.2 of the Das 2.2.1 ICD. Leading zeros are ignored.	

Table 8.1: TASK CACHE - Task Specific Fields

The following string provides an example of a cache 2.2 task request:

2015-03-25T10:37:43.334|jupiter||128.255.33.104|US,Iowa,Iowa City||TASK CACHE| juno/fgm/MagComponentsSCSE||2014-01-01|2014-01-02|ALL

#### 8.1.2 Record Access Task

Job Category Value: TASK\_USAGE

Access event tasks are meant to record which datasets are being retrieved. The Job specific fields are given in Table 8.2 below.

Overall Field Index	Job Field Name	Job Field Description
7	dataset	The name of the dataset that needs to be cached. This is always the relative DSDF filename without the extension. Examples: juno/wav/survey, voyager/1/pws/SpecAnalyzer-4s-Efield
8	begin_index	The beginning index to cache, for Das 2.2 this is an ISO-8601 start time.
9	end_index	The ending index to cache, for Das 2.2 servers this is an ISO-8601 end time.
10	params (optional)	A non-indexing parameter string. Some readers take parameters that are not part of the start and stop period of the data cache.
11	resolution	The floating point resolution datum requested from the client, or empty if no specific resolution was specified.
12	interval	Some datasets are produced at required intervals only. If such a dataset was accessed this field records the interval, otherwise it is blank.

Table 8.2: TASK\_USAGE - Task Specific Fields

The following string provides an example of an access log request for the Voyager spectrum analyzer distogram reader:

2015-03-25T10:37:43.334|planet||128.255.33.104|US,Iowa||TASK USAGE| 

#### 8.1.3 Update Coverage Plot

Job Category Value: TASK\_COVERAGE

D	C	• 1	1 4 4		1 4	41 .	,	4	1 4	C 41	• ,	1 4
P	vServer ca	an provide	dataset	coverage i	าเกร	this wor	k item re	edilest an	undate	ot those	inventory	/ niots
	y Der ver et	an provide	aataset	coverage	orous,	tillo vi Ol	ix itelii i c	equest an	apaate.	or those	III V CIIICOI	prous.

Overall Field Index	Job Field Name	Job Field Description
7	dataset	The name of the dataset whose coverage needs to be updated, or the keyword <b>ALL</b> , to indicate that coverage for all datasets should be updated.
8	begin_index	The beginning time for finding data coverage
9	9 end_index The ending time for finding data coverage.	

Table 8.3: TASK COVERAGE - Job Specific Fields

The following string provides an example of a massive coverage plot update.

```
2015-03-25T10:37:43.334|planet||128.255.33.71||cwp|TASK COVERAGE|||1977-01-01|
2016-01-01
```

## 8.2: In-Process List: das2 working proc-id

Each *instance* of das2 srv arbiter uses a single list to record jobs in process. The current version of the arbiter is single threaded, so at most one item will appear in a das2\_working\_NNNNN list, it's format is:

```
req time|server|server ex|client|client ex|user|job cat|job specific...|begin|
status|progress
```

The working list just adds two fields to the end of which-ever job type is in progress. These are:

- -3: begin An ISO-8601 time indicating when the job was started.
- -2: status Current job status message. (optional)
- -1: progress A fraction giving how much of the job is completed, where 1.0 is the entire job. The fraction may be specified as a fraction using the '/' sign to separate two numbers.

Here is an example of a coverage plot task item value.

```
2015-03-25T10:37:43.334|planet||128.255.33.71||cwp|TASK_COVERAGE|||1977-01-01|
2016-01-01|2015-03-25T10:37:44.512|Updating cassini/mag/4-vec|32/114
```

## 8.3: Result List: das2 finished

Finished items end up in a single list for the entire site. This list persists until cleared by a logger. These items are identical to In-Process items with the exception that the progress value is replaced with an end time.

```
req time|server|server ex|client|client ex|user|job cat|job specific...|begin|
status|end|return code
```

- -4: begin An ISO-8601 time indicating when the job was started.
- -3: status End status message. (optional)
- -2: end An ISO-8601 time indicating when the job finished.
- -1: return code The finial return code from the handling the work item. To continue the tradition set long ago, 0 indicates success non-zero is a failure code.

2015-03-25T10:37:43.334|planet||128.255.33.71||cwp|TASK\_COVERAGE|||1977-01-01| 2016-01-01|2015-03-25T10:37:44.512|Generated coverage map for all 114 datasets.|2015-03-29T01:14:55.512|0

## **Appendix A: Listing Data Sources in DaCHS Servers**

## **Appendix B: Listing Data Sources in Das2 Catalogs**
